Safety Instructions

This unit has been designed and tested in accordance with the EC Certificate of Conformity and has left the manufacturer's plant in a condition fully complying with safety standards.

To maintain this condition and to ensure safe operation, the user must observe all instructions and warnings given in this operating manual.

Safety-related symbols used on equipment and documentation from R&S:

Observe operating instructions

Weight indication for units > 18 kg

PE terminal

Ground terminal

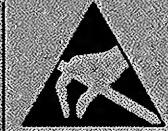

Danger! Shock hazard

Warning! Hot surfaces

Ground

Attention! Electrostatic sensitive devices require special care

1. The unit may be used only in the operating conditions and positions specified by the manufacturer. Unless otherwise agreed, the following applies to R&S products:
IP degree of protection 2X, Pollution severity 2, overvoltage category 2, altitude max. 2000 m.
The unit may be operated only from supply networks fused with max. 16 A.
2. For measurements in circuits with voltages $V_{ms} > 30 V$, suitable measures should be taken to avoid any hazards.
(using, for example, appropriate measuring equipment, fusing, current limiting, electrical separation, insulation).
3. If the unit is to be permanently wired, the PE terminal of the unit must first be connected to the PE conductor on site before any other connections are made. Installation and cabling of the unit to be performed only by qualified technical personnel.
4. For permanently installed units without built-in fuses, circuit breakers or similar protective devices, the supply circuit must be fused such as to provide suitable protection for the users and equipment.
5. Prior to switching on the unit, it must be ensured that the nominal voltage set on the unit matches the nominal voltage of the AC supply network.
If a different voltage is to be set, the power fuse of the unit may have to be changed accordingly.
6. Units of protection class I with disconnectible AC supply cable and appliance connector may be operated only from a power socket with earthing contact and with the PE conductor connected.
7. It is not permissible to interrupt the PE conductor intentionally, neither in the incoming cable nor on the unit itself as this may cause the unit to become electrically hazardous.
Any extension lines or multiple socket outlets used must be checked for compliance with relevant safety standards at regular intervals.
8. If the unit has no power switch for disconnection from the AC supply, the plug of the connecting cable is regarded as the disconnecting device. In such cases it must be ensured that the power plug is easily reachable and accessible at all times (length of connecting cable approx. 2 m). Functional or electronic switches are not suitable for providing disconnection from the AC supply.
If units without power switches are integrated in racks or systems, a disconnecting device must be provided at system level.
9. Applicable local or national safety regulations and rules for the prevention of accidents must be observed in all work performed.
Prior to performing any work on the unit or opening the unit, the latter must be disconnected from the supply network.
Any adjustments, replacements of parts, maintenance or repair may be carried out only by authorized R&S technical personnel.
Only original parts may be used for replacing parts relevant to safety (eg power switches, power transformers, fuses). A safety test must be performed after each replacement of parts relevant to safety.
(visual inspection, PE conductor test, insulation-resistance, leakage-current measurement, functional test).

continued overleaf

Safety Instructions

10. Ensure that the connections with information technology equipment comply with IEC950 / EN60950.
11. Lithium batteries must not be exposed to high temperatures or fire.
Keep batteries away from children.
If the battery is replaced improperly, there is danger of explosion. Only replace the battery by R&S type (see spare part list).
Lithium batteries are suitable for environmentally-friendly disposal or specialized recycling. Dispose them into appropriate containers, only.
Do not short-circuit the battery.
12. Equipment returned or sent in for repair must be packed in the original packing or in packing with electrostatic and mechanical protection.
13. Electrostatics via the connectors may damage the equipment. For the safe handling and operation of the equipment, appropriate measures against electrostatics should be implemented.
14. Any additional safety instructions given in this manual are also to be observed.

7.1Function Description7.1.1Attenuator with Overvoltage Protection

The attenuator is connected between the output module and the instrument output. It is used to attenuate the signal in steps of 5 db. It consists of six attenuator pads of 5, 10, 2*20 and 2*40 dB, an overvoltage-protection substrate and a 50-Ohm terminator. The attenuator pads can be switched on or bypassed by means of one contact group each, which consists of three individual contacts. Each of these contact groups is actuated by a rocker, which is driven by a magnetic coil and kept in end position by a permanent magnet.

The overvoltage-protection substrate and the output switch are situated on the attenuator subsequent to the attenuator pads. The output switch is opened immediately in case of overvoltage and with switching off the instrument (ACFAIL signal).

The overvoltage protection protects the attenuator pads and the output amplifier against exceeded RF and DC voltages, which may be applied to the RF socket. In conjunction with the integrated detector, a diagnosis of the attenuator pads with the associate contact groups can be carried out.

7.1.2Control of the Attenuator Pads

The attenuation of the attenuator is set via serial data transmission by means of the instrument-specific "SERBUS" interface. The buffer memory keeps the voltage for a few ms; the polarity of the voltage in the magnetic coils actuates the contact rockers in either of the two directions. (cf. fig. 1). For the state where the voltage is zero the same polarity is applied to the other relay contacts.

7.1.3Control of the Overvoltage Protection

An overvoltage applied to the output socket is detected by peak rectification on the overvoltage-protection substrate. The comparator N1 responds and directly actuates the output switch Z9 at E7-A7 via D4. The PIN diodes on the overvoltage-protection substrate short-circuit the overvoltage during the response time of the output switch Z9. For this purpose, a high DC current is impressed upon the PIN diodes via the two monoflops V1 and V2. The controller is informed on the overvoltage via the SERBUS INTerrupt.

7.1.4Diagnosis

The diodes on the overvoltage-protection substrate are operated via D9 as peak rectifiers. The rectified voltage is then available on the diagnostic line DIAG-5V. The attenuator pads with the associate contact groups can thus be checked.

7.2

Test Instruments and Utilities

Dual-channel storage oscilloscope 100MHz	e.g., BOS
Network analyzer up to 3GHz	e.g., hp8753
50-Ohm SMA terminator up to 3GHz, VSWR<1.1	
Power-signal generator 25dBm	e.g., SMGL, SMLU
Voltmeter	e.g., UDL33
High-precision attenuator 0 to 120dB, res. 0.1dB	e.g., DPSP
Test receiver 100MHz, sensitivity <0dBuV	e.g., ESV

7.3

Troubleshooting

Output level cannot be set

Check the control code of the individual attenuator pads according to 7.4.3. Do the control pulses correspond to fig. 1

The output switch does not open with switching off the instrument

Check the ACFAIL signal and the control of the output switch acc. to 7.4.4

7.4

Testing and Adjustment

7.4.1 Adjustment of the Attenuator Pads

- Connect network analyzer to X2 (=gate1) and X1 (=gate2).
- Settings: **LEVEL 13dBm**
VSWR measurement: It must not exceed the value 1.35 up to 1.5 GHz and the value 1.5 from 1.5 GHz to 3 GHz
Measurement of the transmission loss: It must not exceed 0.4 dB with 1 MHz. The permitted maximum value shall linearly increase to 2.2 dB up to 3 GHz. Store the measured curve and use as reference value (0dB). Carry out the following steps for each of the attenuator pads Z1 to Z6 (setting via "DIRECT_MODE"): check the attenuation characteristic and adjust in the frequency range 1 to 3 GHz using a grub screw. Make sure that
 - a.) the deviation from the rated value is minimum across the entire frequency range and
 - b.) the maximum pos. and neg. deviations from the rated value have the same absolute value (e.g., +-0.5dB).
 The max. permitted deviation from the rated value of attenuation is +-0.2dB. Finally, check the 50-Ohm terminator (Z9), by means of setting the attenuator to 0dB transmission, RF-OFF, (via "DIRECT-MODE") and measuring S11. The max. permitted reflection coefficient is 40% (VSWR=2.5).

7.4.2 Testing the Overvoltage Protection

Prevoltage of the protection diodes:

- The check is carried out without an RF power being applied
- Settings: **LEVEL 13dBm**

Measure the DC voltage at the loop-through filters Z10 and Z11 or X20 A and X20 B. V at Z10: 2.9V+-0.2V; V at Z11: -2.9V+-0.2V.

- Settings: **DIAG STATE ON**
 TPOINT 1100
Measure the DC voltage at the loop-through filters Z10 and Z11
and X20 A and X20 B. V at Z10: -0.4V+-0.2V; V at Z11: -2.9V+-
0.2V

7.4.2.1 Testing the Response Threshold

- Settings: LEVEL 13dBm

RF check:

Apply a signal of 25MHz, 20dBm to the output X1. Increase level until the overvoltage protection just responds. It must be between 24.5 and 26.5dBm.

Checking the DC voltage:

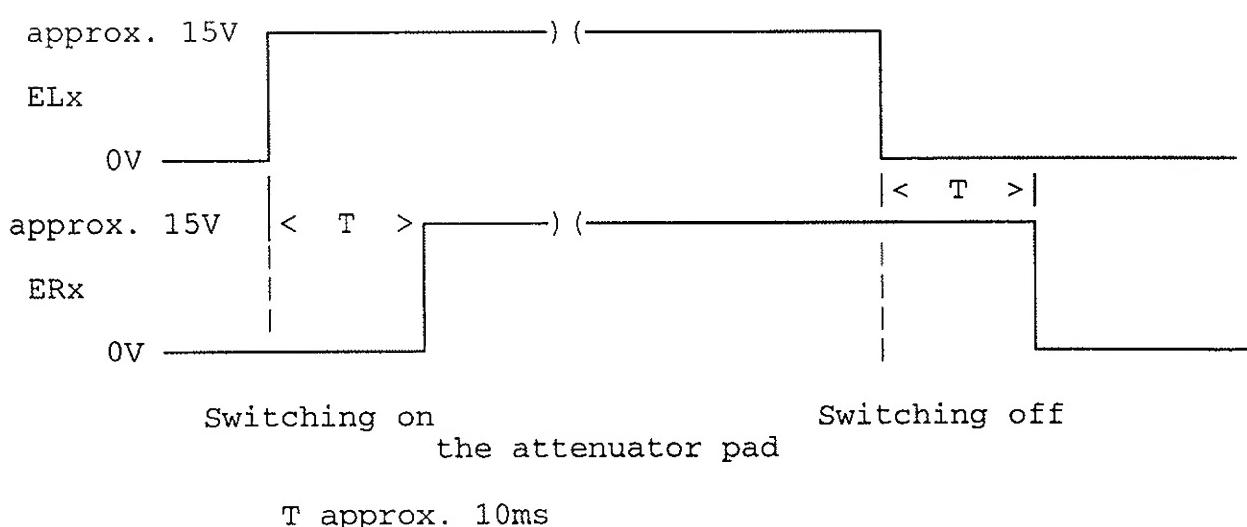

Apply +6V to X1 via a 50-Ohm resistor. The output switch Z9 must open with positive and negative voltages.

7.4.3 Testing the Control Pulses

- Connect an oscilloscope to the respective ELx or ERx-outputs. Set level according to the table below and check the control pulse acc. to fig. 1:

LEVEL [dBm]	Attenuator pad
13	-
8	Z3
3	Z5
-7	Z4
-27	Z6
-67	Z1 (+Z6)
-107	Z2 (+Z1+Z6+Z4)

Fig. 1 Control Pulse of the Attenuator Pads

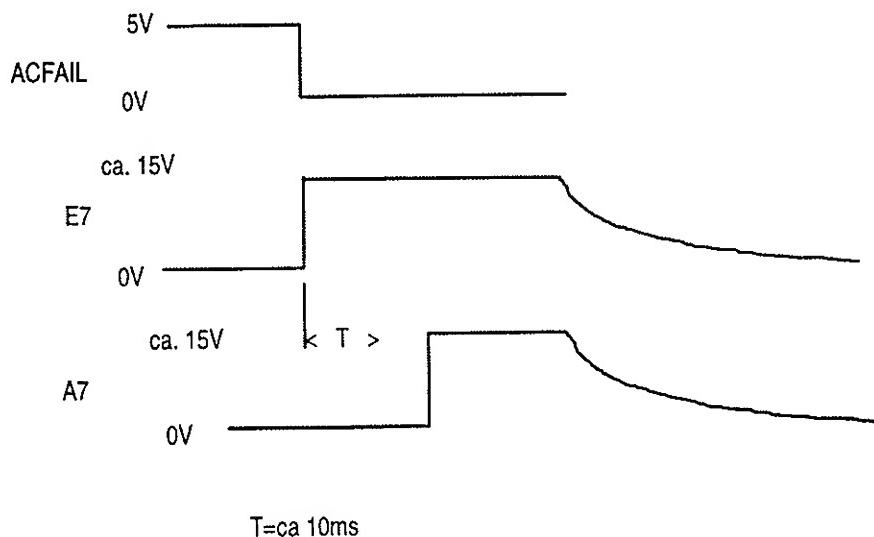

7.4.4

Testing the Output Switch

- Connect an oscilloscope to W150.2 (ACFAIL), E7 and A7.
- Switch off the instrument.
Check according to fig. 2.

Fig. 2 Control pulse with instrument switch-off
=====

7.5

Removal and Assembly

To remove the attenuator, take off the panelling and unscrew the front module. Disconnect the RF cable from X2 and the ribbon cable at X15. The complete attenuator including the clips can be removed after undoing 4 screws on the side brace and one screw at the bottom. Disconnect the cable at X20 and carefully withdraw the control subsequent to undoing 4 screws on the mechanical attenuator. Make sure with assembly that the pins on the mechanical attenuator are not bent when plugging in the control unit.

Note: The max. torque at the SMA connectors X1 and X2 must not exceed 100 Ncm!

Component plan

7.1Function Description

The module "Noise Generator and Distortion Simulator (Option SMIQB17, NDSIM for short) can optionally be connected into the complex modulation signal (I and Q) path of the SMIQ. Depending on the configuration and the operating mode, the modulation signal may be derived from the modulation coder module (Option SMIQB10, MCOD for short), from an external source or from the fading simulator module (Option SMIQB14, FSIM for short). With the NDSIM switched on, the analog input signal is converted into a digital one (AD converter), purely digitally influenced according to the noise or distortion selected and finally converted into a complex analog signal again by DA converters. The complex output signal (I and Q) is routed to the IQ modulator (IQMOD module) and to the AUX connector at the rear panel.

7.2Servicing Concept

The module is a complex hybrid circuit with a prevailing digital section. Therefore, exact fault diagnosis at the component level or repair is not possible at the subsidiaries or at the customer's. A module found to be defective must be replaced by a spare module. Leave the defective module at the production for exact diagnosis and error elimination.

The same applies to the adjustment.

This document is therefore designed to enable the service engineer to clearly identify a defective or incorrectly adjusted module.

7.3Measuring Equipment and Accessories

- Spectrum analyzer, frequency range e.g. FSA, FSE
- Signal generator (100 kHz to 5 MHz) e.g. ADS
- DC voltage source (50-ohm load) e.g. ADS
- DC voltmeter (50-ohm load) e.g. URE

7.4Troubleshooting

If the NDSIM does not work properly, call up the selftest first.

- Settings: UTILITIES :TEST :TEST NDSIM

7.4.1

Loading the FPGAs after Switch-on

After switch-on, the three FPGAs on the module are loaded via the serbus interface by the COMPUTER module. If loading was not successful, this is indicated by the volatile error message "ERROR 420 NDSIM FPGA loading failed", which will then enter into the static "Error Page".

7.4.2

Selftest

The complete selftest is composed of several parts, which are executed one after the other. If a fault occurs in one of these steps, the remaining selftest will no longer be carried out, since each step assumes that there have not been any faults in the preceding steps (e.g. it does not make sense to initiate the NDSIM-internal selftest unless all supply voltage could be measured correctly).

7.4.2.1

Testing the Supply Voltages

Part of the supply voltages of the NDSIM are applied externally (via filter sections), part of them can be derived from these external voltages on the module. The voltages can be connected via the diagnostic multiplexer (D47) to the DIAG 5V bus (X600.A19). Using the diagnostic AD converter of the SMIQ, the voltages are checked by the host computer (A3, FRO).

The following voltages are remeasured:

Designation	Permissible range	Test point
3.3 V Voltage supply FPGAs and RAMs	3.15 V <= U <= 3.45 V	TP 2700
3.3V2 Voltage supply FPGAs und RAMs	3.15 V <= U <= 3.45 V	TP 2704
5VD Voltage supply Digital section	4.96 V <= U <= 5.44 V	TP 2703

7.4.2.2 RAM Address Test

This test serves to detect faults in the addressing of the RAMs (short-circuits between address pins, address pins that are not soldered).

The test is carried out as follows:

- 1) The memory cell with address "0000hex" is assigned the pattern "55...55hex".
- 2) "AA...AAhex" is written to all memory cells with the address "0001hex", "0002hex", "0004hex" to "8000hex".
- 3) Then the memory cell with the address "0000hex" is read out again. If there is no fault in addressing, its contents must be unchanged.
- 4) Test steps 1) to 3) are repeated for the addresses "0001hex", "0002hex", "0004hex" to "8000hex" (Walking One Address) in the same way.

7.4.2.3 ADC Inputs of the DISTO1-FPGA (D5)

This test checks whether all ADC inputs of the DISTO1-FPGA are correctly soldered. A static digital signal is applied via SHIFT REGISTER1 (D21, D22, D23) via serbus to the inputs of the FPGA and read in the FPGA. The test is repeated 12 times as "Walking-One-Test", i.e. each of the 12 data lines of each channel is set to "1" once.

7.4.2.4 DAC Outputs of the NOISE-FPGA (D40)

This test checks whether all DAC outputs of the NOISE-FPGA are correctly soldered. A static signal is applied to the outputs with the DAC compensation in the NOISE-FPGA and read with the SHIFT-REGISTER2 (D34, D35, D36, D39) via serbus. The test is repeated 12 times as "Walking-One-Test", i.e. each of the 12 bits of the DAC compensation is set to "1" once.

7.4.2.5 Testing the Shorting Path

In order to test the shorting path of the module, a DC voltage is connected from the module MCOD to the inputs I_MODIN or Q_MODIN. This voltage is tapped at the module outputs I_MODOUT or Q_MODOUT with the aid of the diagnostic multiplexer and taken via the DIAG-5V line to the diagnostic AD converter of the SMIQ for measurement.

7.4.2.6

Testing the Signal Path Inputs

A DC voltage is applied from the module MCOD to the inputs I_MODIN and Q_MODIN. The relays are switched to normal mode on the NDSIM. The AD converters are read out via the Distrol-FPGA and checked.

7.4.2.7

Testing the Signal Path Outputs

In this test, the relays are switched to normal mode. An FPGA-internal test generator provides a constant signal, which is taken via the bridged distortion simulator to the DACs. The noise generator is switched off.

These output voltages of the DACs are tapped at the module outputs I_MODOUT or Q_MODOUT with the aid of the diagnostic multiplexer and taken via the DIAG-5V line to the diagnostic AD converter of the SMIQ for measurement.

7.4.2.8

ADC/DAC Loop Back Test

The FPGA-internal test generator provides a constant signal, which is taken via the distortion simulator to the DAC. The noise generator is switched off. As with the DAC offset compensation, the relays are switched to the feedback path so that the static signal is taken from the test generator via DAC and ADC to the DC calculation in the Distortion1-FPGA.

7.4.2.9

DC Offset Compensation

After the above tests have been performed successfully, the DC offset compensation is finally called up. It can as well be called up individually via the menu. For more details see section 7.5.4.

7.4.2.10

Error Messages of the Selftest

After the selftest has been started, the individual tests are called up one after the other. If a fault occurs, an error message ("NDSIM Error Code", see table below) is output and the selftest is aborted.

Test	NDSIM_ErrorCode
Testing the supply voltages 3.3V FPGA 3.3V FPGA 5.0V supply digital section	Power TP 2700 Power TP 2704 Power TP 2703
Writing & reading of the RAMs StützSteig RAM Mult RAM Noise RAM	Ram: St_St Ram: Mult Ram: Noise
ADC input	ADC in
DAC output	DAC out
Shorting path Iout Qout	Bypass Iout Bypass Qout
Signal path inputs Iout Qout	Signal Iin Signal Qin
Signal path outputs Iout Qout	Signal Iout Signal Qout
ADC/DAC Loop Back	Loop Back

The NDSIM error code is indicated as volatile display in the status line.
 In addition, the following static entry is made on the "Error Page":
ERROR -330 Selftest failed: NDSIM;

7.4.3

Additional Tests

Imbalances in terms of attenuation and group delay of the input and output filters between I and Q path result in a poor suppression of the image spectrum. The image spectrum is located at the same carrier spacing as the useful spectrum, but on the other side.

An excessive offset voltage leads to an excessive residual carrier.

- Settings: Press the PRESET key

```
VECTOR MOD :STATE :ON
NOISE/DIST :SELECT CHARACTERISTIC :TEST
:DISTORTION :ON
```
- Connect the spectrum analyzer to the output AUX IN/OUT I_FADED at the rear.
- Connect the signal generator to the I-input at the front.
- Measure the frequency response from 100 kHz to 5 MHz (500-kHz steps).

Error description	Error elimination
If the module FSIM (SMIQ-B14) is not installed: Frequency response > 0.6 dB (cable: 0.2 dB, filter: 0.4 dB)	The adjustment of the frequency response of the input or output filters was changed. Readjust the NDSIM.
If the module FSIM (SMIQ-B14) is installed: Frequency response > 0.7 dB (FSIM: 0.1 dB)	

- Connect DC voltage source to the I or Q input at the front and apply +0.5 V +- 1 mV and -0.5 V +- 1 mV one after the other.
- Connect DC voltmeter (50-ohm load) to the output AUX IN/OUT I_FADED or Q_FADED at the rear and measure voltage difference from + 0.5 V to - 0.5 V (offset is not considered in the measurement.)

Error description	Error elimination
<p>If the module FSIM (SMIQ-B14) is not installed:</p> <p>Voltage difference < 965 mV Voltage difference > 1005 mV Difference between I and Q channel > 15 mV</p> <p>If the module FSIM (SMIQ-B14) is installed:</p> <p>Voltage difference < 950 mV Voltage difference > 990 mV Difference between I and Q channel > 15 mV</p>	The DC adjustment of the input or output filters was changed. Readjust the NDSTM.

- Use UTILITIES : CALIB: NDSIM to call the automatic offset compensation.
- Terminate the I and Q input with 50 ohms.
- Use DC voltmeter (50-ohm load) to measure the offset voltage at output AUX IN/OUT I_FADED and Q_FADED.

Error description	Error elimination
Offset voltage > 2 mV	Automatic offset compensation defective. Repair the NDSIM.

The following troubleshooting procedure assumes that the MCOD module (SMIQ-B10) is installed and works properly. Besides, the modules IQMOD and IQCON must function properly and data integrity must be ensured.

- Connect spectrum analyzer to RF output.
- Settings: Press PRESET key

DIG.MOD	:STATE :ON
	:SOURCE :SOURCE :PATTERN
	:SYMBOL RATE :800 000.0 sym/s
NOISE/DIST	:SELECT CHARACTERISTIC :TEST
	:DISTORTION :ON

Error description	Error elimination
Image spectrum 100 kHz below the carrier frequency is attenuated with less than 40 dB. However, an attenuation is clearly visible.	Perform above frequency response and DC measurements and readjust or repair the NDSIM, if required.
Image spectrum 100 kHz below the carrier frequency is not attenuated.	I or Q signal path open. Repair the NDSIM.
Intermodulation products. 200 kHz and 300 kHz below and above the carrier frequency are attenuated with less than 55 dB.	Amplifier or converter overdriven or defective. Perform above frequency response and DC measurements and readjust or repair the NDSIM, if required.

7.5 Testing and Adjustment

As already explained under "7.2 Servicing Concept", defective modules are to be sent to the production department for repair and adjustment.

7.5.1 Revision

UTILITIES :DIAG :CONF serves to indicate the revision and the version of the individual modules. The revision (REV) is coded with resistors R469 to R472, the version (VAR) with resistors R204, R467 and R468.

7.5.2 Jumpers

See also the label "JUMPER SETTING" on the screening cover.

Connect X2.2 with X2.3
Connect X3.3 with X3.4
Connect X4.3 with X4.4
Connect X5.2 with X5.3
Connect X8.1 with X8.2
Connect X9.1 with X9.2
Connect X13.1 with X13.2
Connect X15.1 with X15.2
Connect X16.1 with X16.2

7.5.3 Diagnostic Points

- Settings: UTILITIES :DIAG :TPOINT :STATE ON
 :TEST POINT ~~XXXX~~

Test point	Description
TP 2700	3.3 V voltage supply, 3.15 V to 3.45 V
TP 2704	3.3V2 voltage supply, 3.15 V to 3.45 V
TP 2703	5VD voltage supply, 4.96 V to 5.44 V
TP 2701	I_OUT_T, I output signal at X603 and X604
TP 2702	Q_OUT_T, Q output signal at X605 and X606
TP 2705	Ground potential

7.5.4 DC Offset Compensation

UTILITIES :CALIB :**NDSIM** or **NOISE/DIST :CALIBRATION** permits to call up the automatic DC compensation, which is also part of the internal selftest.

7.5.4.1 ADC Offset Compensation

For the ADC offset compensation, the relays 1, 2, 4 and 7 are switched to a 50-ohm resistor. The voltage offset produced in the AD converter and input lowpass is determined for I and Q channel in the Disto1-FPGA (D5) and read by the computer module. The values read are rounded by the host, inverted and written to the Disto1-FPGA.

7.5.4.2 DAC Offset Compensation

For the DAC offset compensation, the relays 1, 2, 4 and 7 are switched to the feedback path. The output of the Noise-FPGA (D40) is switched to "10...0bin" so that the DA converter provides a 0-V output voltage. The voltage offset produced in the DA converter and output lowpass is determined for I and Q channel in the Distol-FPGA and read by the computer module. The values read are inverted by the host, scaled and written to the noise-FPGA.

7.5.4.3

Error Messages of Offset Compensation

The following volatile error messages may occur:

ERROR 180 NDSIM calibration error; ADC offset calibration
ERROR 180 NDSIM calibration error; ADC offset > 64
ERROR 180 NDSIM calibration error; DAC offset calibration
ERROR 180 NDSIM calibration error; DAC offset > 64

In addition, the following static error message is entered into the error page:
ERROR 180 Calibration failed: NDSIM

If the SMIQ is switched on with the Preset key depressed, the calibration data are deleted and the following static error message is entered into the error page:

ERROR -313 Calibration memory lost; NDSIM-run internal calibration

This message is extinguished with the next successful calibration.

7.6

Disassembly and Assembly

After opening the instrument and loosening the mechanical lock on the motherboard, pull off the six coax connections on the module. The module can then be removed from its slot. Loosen screws and remove screening cover. For assembling and replacing the module proceed in the reverse order.

Power Supply Unit IN 1039.1504.00

This module is a subsupplied part. Thus the documentation does not contain the usual R&S identifications. In the case of complaint, we recommend to replace it by a new module or an exchange module.

Order designation: New part: IN 1039.1504.00
 Exchange part: IN 1039.1504.98

Documents of the manufacturer are attached to our documentation. These documents (1039.1304) are valid for power supply unit IN 1039.1504.00.

Repair work at the module may only be executed by trained staff, observing the safety standards applying to works at electronic circuits.

In order to avoid the destruction of ICs due to static charge, antistatic methods (ESD measures) always have to be observed.

In the case of repair down to component level, only original parts may be used. The use of non-original components or the inappropriate execution of repair work might violate safety provisions and lead to liability claims to be refused.

Modules can be obtained directly via the appropriate R&S representative or via Rohde & Schwarz, Zentralservice München.

7. Checking and Repair of the Module

7.1. Function Description

7.1.1 Overview

The rectified, filtered AC supply voltage is down-converted to an intermediate voltage of approx. 140 V using a pulse controller. This intermediate voltage is subsequently chopped by a push-pull stage and applied to the main transformer T1, the secondary windings of which generate 7 out of 8 output voltages by means of series regulators and switching regulators. The standby voltage as well as the internal auxiliary voltages are derived from a separate transformer clocked on the primary side.

The instrument is automatically set to the AC supply voltage value (115/230 V). A filter for suppression of conducted interference is provided at the input. Reliable isolation is achieved by using transformers for power conversion and VDE optocouplers for signal conversion.

The outputs of the secondary circuit are protected against overload and overvoltage. Cooling of the instrument is provided by a thermostat-controlled fan, which achieves its maximum speed only at high ambient temperatures.

7.1.2 Auxiliary and Standby Circuit

The standby transformer is directly operated from the rectified AC supply voltage, i.e. it is in operation as long as the AC supply voltage is applied and the power switch is switched on. The transformer operates in a freely oscillating mode. The oscillations are generated by the components arranged around switching transistor V116 and standby transformer T2. The control is performed by operational amplifier N17 following rectification and filtering of the voltage UH1 from the secondary winding N4 of the standby transformer. UH1 is adjusted to 12.8 V.

The remaining two output windings of T2 are used to generate the internal auxiliary voltages UH4 (+12.8 V, primary) as well as UH3 (+30 V, secondary) by means of rectification and using small series regulators. The +12.8-V auxiliary voltage of the secondary winding is reduced to 12.0 V in a further series regulator (transistor V98), current-limited to approx. 1 A and output as standby voltage (output 6) at the 50-contact connector. In order to prevent the variable transistor from being overloaded in the case of current limiting, the output voltage is totally cut off for approx. 2 seconds in the case of overload.

7.1.3 Primary Power Unit

After the preliminary filter with L32 and C29, the AC supply voltage is taken via a power resistor R75 (for inrush current limiting) to rectifier V45 and is subsequently buffered in the electrolytic capacitors C31, C32, C23. A further filter with L2, C22, C33, L28 and C95 is connected between rectifier and electrolytic capacitors. The DC voltage is applied from the electrolytic capacitors to the pulse controller consisting of transistor V28, choke L1 and commutation diode V64. The switching frequency of the pulse controller of approx. 70 kHz is produced by means of comparator N15. The output voltage is proportional to the pulse duty factor of the signal applied to the switching transistor. The pulse duty factor is set by the main regulator via optocoupler U4 and current comparator N15 depending on the output power and input voltage. The maximum power of the pulse controller is determined by the highest possible pulse duty factor and lies at approx. 300 W. The resulting intermediate voltage (output voltage of the pulse controller) of approx. 140 V is chopped by means of a half-bridge and applied to the primary winding N1 of main transformer T1. Transistors V131, V132 of the bridge are also supplied with 70 kHz via control transformer T3. The main control loop described here is closed by regulator N18, which maintains the secondary voltage of winding N2/N3 of the main transformer UGR+16 at a constant voltage of 15.8 V. Using the optocoupler U2, the pulse controller is switched off in standby mode; the same is achieved by the signal WSP from the primary control in the case of undervoltage.

7.1.4 Primary Control

The primary control generates the sequence of functions when the power supply unit is switched on. After the AC supply voltage has been applied, the auxiliary voltage UH4 must first increase to approx. 10 V so that the further control is enabled by the auxiliary voltage monitoring circuit with transistors V22, V23. Then the AC supply voltage value is evaluated by comparator N1. If the AC supply voltage value has not yet reached the 230-V range after approx. 100 ms (R8, C6, C7 at N1), relay K1 switches in order to achieve doubling of the voltage by cascading the input electrolytic capacitors C31, C32. If the AC supply voltage reaches the 230-V range within 100 ms, N1 remains locked in. Thus, relay K1 remains dropped out, avoiding that the 155-V mode is selected again when the AC supply voltage fails, which would involve a high current inrush.

After the voltage at the input electrolytic capacitors has increased to 240 V, the undervoltage sensing circuit N2 activates a timer (N1, C4, R8, R9) which first short-circuits the resistor R75 for inrush current limiting via K2 and then enables the main transformer via the control signal WSP. The undervoltage sensing device N2 is provided with a hysteresis so that the main transformer is only disabled again when the rectified AC supply voltage has fallen below 160 V.

When the rectified AC supply voltage decreases, N2 informs the evaluation circuit for the ACFAIL signal in the secondary circuit via optocoupler U3.

7.1.5 Secondary Power Unit

The voltages provided by the primary power unit at the secondary windings of the main transformer are separately rectified and filtered. The windings N2/N3 deliver the high-end voltages UGR+16 for +15.3 V, UGR+8 for +7.7 V and UGR-16 for -15.3 V. N4/N5 provides UGR+13 for +12 V, N6 provides the high-end voltage for -30 V and N7 UGR38 for the switching regulator of the 24.5/30 V. These voltages are all rectified and filtered before being applied to the subsequent regulators.

The voltages for the outputs +15.3 V, -15.3 V, +12 V and -30 V are subsequently stabilized by series regulators. Each series regulator consists of a power MOSFET as regulating element with shunt and associated comparator for monitoring the current limiting. The 5.2-V output voltage is regulated by a switching regulator from the UGR+16, the switching frequency of which is synchronized with that of the main transformer.

The output voltage 24.5 V/30 V is generated on a separate module by a freely oscillating switching regulator. The output voltage of this regulator can be set by external connection of the signal COD at the output connector of the power supply, the voltage divider of the variable operational amplifier N3 being switched over. COD open: 24.5 V, COD connected to GND: 30 V.

The output voltage 2 (7.7 V) is not regulated, since only low requirements are placed on stability.

7.1.6 Reference Voltages

All regulators are provided with a common reference voltage REF1 of +5.2 V, which is generated by means of the integrated voltage regulator N18 and adjusted using potentiometer R209. For the regulators of the negative output voltages, a reference with half the value, i.e. +2.6 V (REF3) is additionally obtained from REF1 by voltage division. The reference voltage of +4.94 V (REF5) required for monitoring the +5.2 V with respect to undervoltage is formed by N19 and adjusted by means of R223.

7.1.7 Current Limiting / Overvoltage Protection

The so-called IREG signal constitutes the core of current limiting and overvoltage protection. This signal directly acts on the main regulator, reducing or disabling the total output power of the power supply by increasing the level; this is not true for the standby voltage. The IREG signal combines the outputs of the individual current limitations and overvoltage detectors.

- Current limiting:

The regulators of the output voltages +5.2 V and 24.5/30 V are provided with an independent current limiting facility each that features a constant-current characteristic in the case of overload.

The response of the standby voltage to current limiting is described in the respective section.

The remaining outputs are separately monitored with respect to overcurrent. For this purpose, the voltage dropping across a shunt in the respective current path is compared with a reference voltage by a comparator. If the output current exceeds the predetermined value, the comparator is activated, applying the IREG signal to high potential and thus reducing the power of the main transformer.

- Overvoltage protection:

In order to avoid damage to the loads in the case of accidental short-circuits between the output voltages, the main transformer is deactivated in the case of overvoltage at the outputs.

To this end, the output voltages +7.7 V, +15.3 V, 24.5/30 V, -15.3 V and +12 V are each applied via zener diodes to a common load resistance R221 and grounded. Overvoltage at an output causes a current flow in the appropriate zener diode and thus a voltage drop across R221. As a result of this, comparator N16 switches the IREG signal to high, disabling the main transformer. See also hickup mode. The -30-V output is not monitored. In the case of overvoltage at 5.2 V, a thyristor is triggered, short-circuiting the output voltage.

In order to prevent rising of the output voltages in the case of internal faults, the secondary voltage UGR+16 of the main control loop is separately monitored by comparator N25 and the main transformer deactivated when 17 V are exceeded.

- Hickup mode:

In order to protect the internal circuit and the connected loads from high continuous load due to overcurrent/overvoltage, a timer N26 is started when the IREG signal responds, disabling the main transformer for a few seconds. Thus the output power is maintained at acceptable values on average in the case of continuous disturbance. See also 1.8 Secondary Logic.

7.1.8 Secondary Logic

- Standby switch:

The multiple RC connection at the input of STANDBY/ON, D2 permits to connect power switches and signal switches and is used for debouncing the switch. The switch position is signalled to the primary side via optocoupler U2 and directly acts on the main transformer and the fan.

- ACFAIL# and SYSRESET#:

The NAND gates consisting of D3 generate the signals ACFAIL# and SYSRESET#.

ACFAIL# goes logic high after switching on of the power supply as soon as the 5.2-V output voltage has achieved 4.94 V and the 15.3-V output voltage has increased to 14.5 V. On power failure, ACFAIL# is set to logic low by the primary control via optocoupler U3.

When the power supply unit is switched on, SYSRESET# is delayed by approx. 300 ms by the RC section R324, C108 compared with ACFAIL#. On power failure, SYSRESET# is set to logic low as soon as the 5.2-V voltage has decreased to 4.94 V.

- Hickup mode:

The hickup mode mentioned in connection with current limiting includes the following functions:

When the unit is switched on, the main transformer is first enabled by timer N26 via optocoupler U2. If the +15.3-V output voltage has not yet increased to 14.5 V after 2 seconds, the main transformer is disabled for 6 seconds and subsequently enabled again for a new cycle. In the case of current limiting or overvoltage, the +15.3-V output voltage collapses to values below 14.5 V, and the same process is released.

7.1.9 Miscellaneous

The NTC R248 controls the fan speed via V143 depending on the temperature inside the instrument. At temperatures below 50°C, the fan is operated with approx. 7 V, this voltage increases to maximally 10 V at temperatures up to 60° and then remains constant. Using the NTC R184, an overtemperature protection has been implemented that deactivates the main transformer at more than 75°C.

7.2

Measuring Instruments and Auxiliary Equipment

Variable isolating transformer with at least 500 VA,
Laboratory power supply with DC voltage output 0 to 40 V,
DC voltmeter (digital multimeter).

7.3

Troubleshooting

- Note:

Repair work on the open instrument may only be carried by trained personnel. An isolating transformer must be used for current supply. Note that the circuit includes live parts and that, due to charged electrolytic capacitors, the input section carries dangerous contact voltages for approx. another 2 minutes even after the current supply has been interrupted!

To facilitate troubleshooting, the output voltages of the power supply should be monitored using digital voltmeters. The description of the causes of faults in most cases indicates several possible faults of components which may be responsible for the respective error symptom. Check these components and replace, if necessary, using the types of components indicated in the part lists.

Fault: Input fuse is blown when AC supply voltage is applied.

Causes:

- Switching transistor V28 of pulse controller faulty,
- Free-running diode V64 faulty,
- Diode V63 faulty,
- Rectifier V45 faulty.

Fault: no output voltage, fan does not run.

Causes:

- Fusing resistor R211 faulty,
- Switching transistor V116 of standby transformer faulty.

Fault: Only standby voltage provided.

Causes:

- Open circuit in the lead from the standby switch,
- Open or short circuit in the signal path from the terminal of the standby switch via the debouncing circuit preceding D2, via optocoupler U2 to the pulse controller,
- Level of WSP signal in the pulse controller is 0 V: Fault in the primary logic,
- Level of IREG signal exceeds 0 V: Find the source, see fault output voltages in hickup mode.

Fault: output voltages in hickup mode.

Causes:

- Fault in current limiting or overvoltage protection circuit. All feeding comparators are decoupled from each other via diodes and can therefore be investigated separately. The comparators of the current limitation of the analog regulators are the main possible causes; they are listed in the following:

+15.3V : N22 pin 1,
+7.7V : N17 pin 1,
-30V : N21 pin 1,
-15.3V : N20 pin 7,
+12V : N14 pin 7,
Overvoltage: N16 pin 7.

- A faulty function of the current comparators may be due to an open circuit in the shunt or a faulty resistor in the voltage divider at the input of the comparator.
- A faulty function due to overvoltage sensing can be caused by a short circuit in the variable transistor or a faulty resistor in the regulator voltage divider.

Fault: Missing output voltage.

Causes:

- Open circuit in the winding of the transformer,
- Faulty rectifier diodes,
- Faulty series regulator transistors,
- Open circuit in shunt,
- Faulty resistor in regulator voltage divider.

7.4 Putting into Operation

The AC supply voltage is delivered via a variable transformer. Increase the voltage to 110 V, the instrument is activated. Use R209 to set the output voltage 1 to 5.20 V on the instrument without load connected. Use R223 to set the voltage at pin 1 of the 50-contact connector to 4.94 V. Increase the AC supply voltage to 230 V, instrument switches over to 230-V operation (switching of internal relay can be heard) and continues running. All output voltages must then be provided according to the description of the external interfaces. To check proper functioning of the overvoltage protection, an overvoltage is simulated from outside using a laboratory power supply with the instrument running. The involved voltages are +5.2 V, +7.7 V, +15.3 V, -15.3 V, +12 V and 24.5/30 V. For this purpose, apply a voltage that is approx. 25% above the rated value to the respective output, the power supply must shut down immediately.

7.5 Disassembly and Assembly

Disassembly:

Loosen 6 screws on the circumference of the cover, pull off the cover towards the rear.

Loosen 4 screws at the front of the instrument, remove the connector of the fan terminal and of the connection from the power terminal to the printed circuit board.

The major test points are then accessible.

Assembly:

Check that the printed circuit boards are properly insulated. For the assembly, proceed in the reverse order.

7. Testing and Repair of the Module

7.1 Functional Description

The Reference Oscillator Option OCXO replaces the internal 10-MHz time base by an oven-controlled high-quality crystal oscillator, which considerably improves the instrument data with respect to accuracy of reference frequency and aging.

In addition to the oscillator proper, the module includes components for internal data transmission (D1), data storage (D30) and diagnosis (D40) as well as a switchable output amplifier (V70 and V71). Version 06 also includes a circuitry for generation of the interrupt for the "OVEN COLD" indication (N50,N60).

The oscillator remains switched on in standby mode.

7.2 Measuring Equipment and Assembly

DC Voltmeter e.g. UDS 5, URE

RF spectrum analyzer up to 100 MHz e.g. FSA

Calibrated frequency counter 10 MHz (included in FSA)

Laboratory oscilloscope with approx. 100-MHz bandwidth

7.3 Troubleshooting

Frequency error Trace the tuning voltage as far as to the oscillator. Recalibrate in the case of small deviations due to aging (see section 7.4.5).

Level error Trace control signal OSCOFF. Check operating point of output stage. Check output level of oscillator (see section 7.4.2.)

7.4 Testing and Adjustment

7.4.1. Current Consumption, Data Transmission

- Switch on cold instrument using the power switch (not from standby mode) and press the PRESET key.

Current consumption at +12V is greater during warmup period and must decrease after 5min (VAR02) or 10min (VAR04/06) at 25 grad Celsius ambient temperature to its settled value.

Current consumption	VAR 02	VAR 04/06
+5V	max. 2mA	
-15V	max. 7mA	
+12V heating	max. 250mA	max. 270mA
+12V settled	max. 130mA	max. 150mA

The module status is encoded by pulldown resistors (R8 to R15) at the parallel port of D1. Open inputs mean "high". The first 4 bits encode the module version, the second 4 bits the modification status.

Version	02	04	06	Status	0	1	2	3	4
Decimal value	1	2	3		0	1	2	3	4

The version/status values in question must be indicated corresponding to fitted resistors in the display when the menu UTILITIES/DIAG/CONFIG is selected.

7.4.2. Testing the Oscillator and the 10-MHz Amplifier

- SME setting: PRESET
- The control bit OSCOFF must show "low" potential. The output stage V71 is active, the DC operating point is to be at 5 ±2 V. The signal must reach TTL level at the oscillator output (use oscilloscope for high-impedance measurement).
- Connect spectrum analyzer to X771. The 10-MHz signal is to feature an amplitude of 7.5 ±1.5 dBm and a harmonics suppression >15 dB.
- Select OSC/SOURCE EXTERN in the menu UTILITIES/REF.
- The control bit OSCOFF must go to "high" potential, V70 becomes conducting and disables the output stage. The collector voltage of V71 increases to 12 ±1 V. The output signal at X773 must fall below -50 dBm.

7.4.3. Testing the Interrupt Generation (Message OVEN COLD)

As long as the oven of the crystal oscillator has not yet reached nominal temperature, a "high" signal is applied to the input IRO (pin 39) of the data transmission component D1. This is recognized by the controller in the front module, and the message "OVEN COLD" is produced on the display.

Versions 02 and 04 :

- With jumper X50 removed, the "OVEN COLD" message must not be caused. If X50/2 is set to "low", an interrupt and thus the message "OVEN COLD" must appear.
- Insert the jumpers on X50/1-2 and X40/1-2.

- An oscillator after warmup (after approx. 5 to 10 minutes at 25 degrees) must not produce the "OVEN COLD" message, whereas one that has just been switched on must. An oscillator after warmup must again signal "OVEN COLD" after it has been switched off for some minutes (power off, not standby!).

Version 06 :

- Remove jumpers X40 and X50, apply a DC voltage of 0 to 12 V to X40B. Observe logic level at X60A.
- High level must appear with a DC voltage below 5.6 ± 0.1 V, "low" up to 6.4 ± 0.1 V and "high" again above this value.
- Replace jumper X60. Check on the display whether the message "OVEN COLD" appears when varying the DC voltage.
- Measure the voltage at X40A using the voltmeter (after 5 min operation), nominal value 6.0 ± 0.2 V.
- Replace jumpers X40 and X50.
- An oscillator after warmup (after approx. 5 to 10 minutes at 25 degrees) must not produce the "OVEN COLD" message, whereas one that has just been switched on must. An oscillator after warmup must again signal "OVEN COLD" after it has been switched off for some minutes (power off, not standby!).

7.4.4. Testing the Diagnosis

The module must be allowed a warmup time of approx. 5 minutes before the measurement.

- Select ON in the menu UTILITIES/DIAG/STATE. Check the following test points (TPOINT):

Test point	Nominal voltage/V
101	6 ± 0.6 only vers. 06
102	2 ± 0.5

7.4.5. Adjusting the Oscillator

- Connect calibrated frequency counter to the REF socket on the rear panel and measure the output frequency. The instrument must have been in operation or in standby mode for at least 2 hours.

Versions 02 and 04:

- First set in the menu UTILITIES/PROTECT LOCK LEVEL 2 to OFF by typing the password 250751.
- Select REF OSC in the menu UTILITIES/CALIB. Then select CALIBRATION DATA AND vary using the rotary knob until the nominal frequency of 10.000000 MHz is obtained. The new setting

value is written into the EPROM by means of "STORE CALIBRATION DATA".

CAUTION!! This procedure can only be repeated until the memory area reserved in the EPROM is used up. In this case, the flash EPROM must be cleared and written to again by a R&S service department.

Version 06 :

The oscillator of version 06 is mechanically adjusted.

- For this purpose, remove the panelling (see section 6.5).
- The nominal frequency of 10.000000 MHz can be set by means of the trimmer on the lateral surface of the oscillator housing.

7.5 Disassembly and Assembly

Remove instrument panelling (see service instructions for complete instrument SME, section 6.5)

Unlock flat cable connector X22 on the motherboard and remove.

The module is fastened in the slot on the righthand side of the instrument with four screws. Remove the screws and pull out the module so that RF cable W170 can be removed.

Loosen the cable clamp on the flat cable and take out the module.

For replacing the module, proceed in the reverse order.

7.6 External Interfaces

Pin	Name	Inp./Output	Origin/Destination	Value range	Signal description
X22.4,8,10,14,15					Ground
X22.16	OPTTUNE	Input	A7	0..12V	Tuning voltage

7.1 Functional Description

The "FMOD" module provides the analog frequency and phase modulation. It can be fitted optionally. The output signal of the module "Digital Synthesis" (input X67, FDSYN) is modulated with the FM/PHIM signal and is then passed to the "Summing Loop" (output X69, FDFM). The reference frequency 100 MHz for the control loops is supplied by the "Reference/Step Synthesis" module (input X65, REF100).

The module can be divided into three function units:

- FM-deviation attenuator with the function blocks SWITCH MATRIX, DEVIATION ATTENUATOR, PREEMPHASIS, BUFFER and DEVIATION ADJUSTMENT
- FM and PHIM control loops with the function blocks FM OSCILLATOR, FM LOOP INTEGRATOR, FM BUFFER, FM DIVIDER, REFERENCE DIVIDER, PHASE DETECTOR, IMPULSE SWITCH, PHIM PLL and CONTROL VOLTAGE for PHIM
- Mixer stage with the function blocks LO AMPLIFIER, MIXER1, BANDPASS FILTER, MIXER2 and OUTPUT AMPLIFIER

7.1.1 FM-Deviation Attenuator

The four AF inputs EXT1, EXT2, INT1 and INT2 are provided for the input of the modulation signals. The AC/DC isolation for the two external modulation inputs is effected by the switch D200. The modulation signals are applied individually to one of the two modulation channels via the switches D210, D215 and D220. Either single-tone or dual-tone modulation are possible.

The amplifiers N220 and N230 provide the signals for the dual-channel D/A converter D240, which sets the fine deviation at a resolution of 12 bits, each. The subsequent summing amplifier N240 adds the signals of the two modulation channels.

The modulation signal FMGROB is passed via the subsequent deviation attenuators D250 either directly or via the distortion circuit PREEMPHASIS to the FM-PHIM switch D480. Subsequent to passing the DEVIATION ADJUSTMENT (N490) and the range switch (FMRANGE), the control signal U-MOD passes to the FM OSCILLATOR.

The signals PHIMREF and FMREF for the PHIM or the FM control loop are decoupled by means of the BUFFER AMPLIFIER N260.

The level on EXT2 is monitored by the window comparator N280, which supplies an interrupt (INT1) if the level differs from the rated level ($1V_S$) by $\pm 2\%$, if it is operated in the EXT-AC mode. This window voltage implies a tolerance of $\pm 1\%$. The signals EXT2-HIGH or EXT2-LOW indicate the respective status.

7.1.2 FM and PHIM Control Loops

The 100-MHz VCO (FM OSCILLATOR) provides two tuning inputs. The centre frequency is readjusted via the tuning diode V328, the actual modulation is effected by the diodes V318-V327.

The VCO can be operated in two control loops. If FM is selected, the oscillator is readjusted in a slow frequency control loop with approx. 2-Hz bandwidth. In this case, the modulation is outside the control bandwidth.

If PHIM is selected, the modulation is carried out in a phase-locked loop with a control bandwidth of approx. 300 KHz. The

tuning voltage of frequency adjustment is stored in order to ensure that the phase-locked loop operates also in the linear characteristic range of the deviation diodes. This is effected via the window comparator N455, which compares the FM control voltage and the control voltage for PHIM during FM operation and which supplies control signals (COUNT1, COUNT2) in case of deviation. The control signals trigger an 8-bit counter in the gate array FMDCSYNC which corrects the tuning voltage for PHIM via the 8-bit D/A converter D450, thus minimizing also the settling procedure with switching back to FM.

The oscillator signal and the 100-MHz reference signal are divided by the factor 10 by the FM DIVIDER and the REFERENCE DIVIDER and then applied to the PHASE DETECTOR D410.

If the frequencies differ, one of the two outputs supplies a pulse sequence, the duty factor of which changes according to a sawtooth (P401, P402). The repetition frequency is the difference frequency. The sawtooth voltage is obtained by lowpass filtering, it is differentiated (C404, C405) subsequently and supplied to the gate array FMDCSYNC as trigger signals.

The gate array supplies pulses (A, B, C) derived from the reference frequency PFD2 with two pulse durations selectable via FM-RANGE, which correspond to the two deviation ranges. Depending on the frequency offset, either a positive or negative voltage with this pulse duration is passed by D420 via the range switch D430 to the FM-LOOP INTEGRATOR N430. Between the pulses, an analog control current is applied to the integrator via C406 and C410.

The modulation signal FMREF decoupled via N260 and D270 is also applied to the integrator with inverted sign, thus allowing for FM-DC modulation. The control voltage then only changes, if the average timings of the two signals are different.

In the PHIM operating mode, the FM control loop is switched off by means of the control signal PHIMOD and the PLL is switched on (D415).

In case of a phase difference, one output of the phase detector provides a pulse sequence, the mean value of which increases linear with increase of the phase difference. This sequence is superimposed by the modulation voltage. The phase detector is not operated in its zero point, in order to obtain a minimum PHIM distortion factor. (Adjust the distortion factor using R244).

The modulation signal PHIMREF is applied to the PLL in the subsequent PHIM PLL (summing amplifier N475 and control amplifier N480) and the sum signal passes via the amplifier N490 to the FM OSCILATOR.

The FM MONITOR (N300) or the PHIM MONITOR (N485) watch the respective control voltage and trigger an alarm, if one of the PLLs unlocks (Serbus interrupt).

The modulated signal FMMOD is decoupled via the FM BUFFER and, subsequently, is passed as LO signal to the mixer stage.

7.1.3 Mixer Stage

Since the input frequency of the digital synthesis FDSYN must be retained, it is first up-converted by means of the fixed frequency REF100 (MIXER1). The LO-AMPLIFIER V510 supplies the required LO level of the reference signal.

The BANDPASS FILTER (110 to 120 MHz) between MIXER1 and MIXER2, which is required for suppression of the reflection band and other spurious signals is realized by a combination of highpass and low-pass filters isolated by the stages V540 and V550. This combination consists of two Cauer highpasses of 7th order and one Cauer

lowpass of 7th order, the latter minimizes the group delay distortion of the DDS signal.

The modulated 100-Hz signal FMMOD is down-converted at the MIXER2 such that the input frequency is obtained again. The amplifier V575 is followed by a pin-diode switch (V580-V582), which through-connects the signal to the OUTPUT AMPLIFIER with modulation switched on. When modulation is switched off, the signal FDSYN is passed by directly to the OUTPUT AMPLIFIER.

The signal is routed to the output socket X69 via a lowpass which suppresses the harmonics.

7.2 Measuring Equipment and Accessories

- RF spectrum analyzer (e.g., FSA)
- Modulation analyzer including distortion and level meters (e.g., FMA)
- Function generator, 10 Hz to 2 MHz (e.g., AFS)
- AF voltmeter, 10 Hz to 2 MHz (e.g., URE)
- DC voltmeter, 5-digit (e.g., UDS5)
- Oscilloscope, frequency range > 300 MHz
- Service kit (1039.3520)

7.3 Troubleshooting

The rated values of the diagnostic points, which are checked during troubleshooting procedures, are given in Section 7.4.7.3.

7.3.1 Errors with Frequency Modulation

FM control loop beyond the tolerance

Error message "FM MODULATOR FAILURE"

Check, if the control voltage is out of tolerance using diagnosis 501, otherwise, the FM MONITOR is faulty

Read diagnosis 505 (FM1/2 SOURCE OFF). The offset voltage measured must be small, otherwise, check deviation attenuator according to Section 7.4.2.

Check FM OSCILLATOR acc. to 7.4.3.1

Set FM OSCILLATOR to 100 ± 0.5 MHz using C329, subsequently, check FM correction circuit acc. to 7.4.5.3.

FM distortion factor too large

Check distortion factor of the modulation signal $f=1$ KHz at X24A and X49BA. If distortion factor is > 0.1%, check FM deviation attenuator or modulation source

Adjust FM OSCILLATOR acc. to 7.4.3.2, then adjust acc. to 7.4.3.3

FM deviation incorrect or FM frequency response too large	Check the FM deviation attenuator according to 7.4.2
FM-DC Centre-frequency deviation too large	Adjust frequency deviation acc. to 7.4.3.3
FM-DC Centre-frequency deviation too large	Read out diagnosis 505 (FM1/2 SOURCE OFF). Only a small offset voltage must be measured, otherwise, check deviation attenuator acc. to 7.4.2.
FM-DC Centre-frequency deviation too large	Adjust FMAC centre-frequency according to 7.4.5.1
Undue residual FM	Adjust FM correction according to 7.4.5.2
Undue residual FM	Check FM correction circuit according to 7.4.5.3
Undue residual FM	Check FM correction circuit acc. to 7.4.5.3
Undue residual FM	Check analog control current at C406 and C410

7.3.2 Errors with Phase Modulation

PHIM control loop out of tolerance	Check, if PHIM MONITOR is faulty, by measuring the voltage at window comparator N485 pin2/5
Error message "PM MODULATOR FAILURE"	Check TUNING VOLTAGE for PHIM, read out diagnosis 501
PHIM distortion factor too large	Check FM OSCILLATOR acc. to 7.4.3.1
PHIM distortion factor too large	Check the PLL according to 7.4.4.3
PHIM distortion factor too large	Check distortion factor of the modulation signal f=1KHz at X24A and N260 Pin6. If distortion factor is > 0.1%, check FM deviation attenuator and modulation source
PHIM distortion factor too large	Adjust PHIM distortion factor acc. to 7.4.4.1
PHIM distortion factor too large	Adjust FM OSCILLATOR acc. to 7.4.3.2, subsequently, adjust acc. to 7.4.3.3

**PHIM deviation incorrect or
PHIM frequency response too
large**

Check FM deviation attenuator ac-
cording to 7.4.2

Adjust phase deviation acc. to
7.4.4.2

Check PLL acc. to 7.4.4.3

7.3.3 Spectral Purity of the Output Signal

**Spurious signals with FM-DC
mode**

Check BANDPASS FILTER acc. to
7.4.6.1

Check BYPASS SWITCH acc. to 7.4.6.2

**Spurious signals with PHIM
mode**

Check bandpass filter (80 to 120
MHz) of the FM BUFFER between V355
and X35

Check bandpass filter (80 to 120
MHz) of the LO AMPLIFIER between
V510 and MIXER1

7.3.4 Level Error of the Output Signal

**No level or level too small
with modulation switched on**

Check FM BUFFER acc. to 7.4.3.4

Check LO AMPLIFIER using diagnosis
503

Check BANDPASS FILTER acc. to
7.4.6.1

Check BYPASS SWITCH and OUTPUT AM-
PLIFIER acc. to 7.4.6.2

**No level or level too small
with modulation switched off
(FM1/2 OFF)**

Check BYPASS SWITCH and OUTPUT AM-
PLIFIER acc. to 7.4.6.2

7.4 Checking and Adjustment

*All measured values without tolerance information are recommended
values. Voltages given without any further designation are DC vol-
tages.*

*The service kit contains an adaptor which can be used to make the
board accessible. The adaptor is inserted into the chassis instead
of the board and, subsequently, the RF connections at the corre-
sponding sockets on the lower side are reconnected. The board can
then be plugged onto the adaptor.*

*When removing the jumper X35 or interrupting the signal lines,
which influence the output frequency, the instrument must be PRE-
SET subsequent.*

7.4.1 Testing Data Transmission and Power Supply

(see circuit diagram, sheets 2 and 7)

According to the instrument standard, the FMOD module is controlled via a serial interface using the component SERBUS-D. The data are transmitted on two different subaddresses. The MSB of each subaddress is transmitted first and is applied to Q8 (Pin 11) of the corresponding latch. The settings and associate data can be looked up in Section 7.4.7.1.

The power consumption of the module can be checked by connecting an ammeter instead of the coils L92, L93, L94 and L105. The rated values for the respective supply voltages can be looked up in Section 7.6.

7.4.2 Testing the FM Deviation Attenuator

(cf. circuit diagram, sheets 3 and 5)

- Apply an AF frequency (given in the table below) of $1 V_s$ to the sockets EXT1 or EXT2 on the front module
- Measure the level at the jumpers X24A or X49B using an AF voltmeter. This level is used as reference for further measurements. All measured values refer to this level.
- Settings:
 - FREQUENCY 1000 MHz
 - FM1 SOURCE EXT1
 - FM2 SOURCE EXT2

Setting (FM DEVIATION1/2)	AF frequency	Measured value X24	Measured value X49
500 KHz	1 KHz	Reference ($2.35 V_s$)	Reference (1.2 to $1.9 V_s$)
	10 Hz	0 to 0.5 dB	0 - 0.5 dB
	2 MHz	0 ± 2 dB	0 ± 2 dB
1000 KHz	1 KHz	0 ± 0.05 dB	6 ± 0.05 dB

7.4.3 Testing and Adjustment of the FM OSCILLATOR

(cf. circuit diagram, sheets 4 and 5)

It is necessary for adjustment of the FM oscillators (7.4.3.2 and 7.4.3.3) that the FM correction works, however, it need not be adjusted.

7.4.3.1 Testing the FM OSCILLATOR

The FM oscillator is checked without setting an FM deviation

- Settings:
 - FM1 SOURCE EXT1
 - FM1 DEVIATION 0 KHz

Test point	Type of signal	Rated value
P302	Supply voltage	11.5 to 12 V
P303	Supply voltage	-12 to -11.5 V
X32AB	Working point of the deviation diodes	5 to 11.5 V
X34AB	RF voltage, VCO	- 20 dBm / 50Ω , approx. 100MHz

7.4.3.2 Adjustment of the Distortion Factor and Presetting of FM Deviation and Control Voltage

- Remove jumper X35 and connect a modulation analyzer incl. distortion and level meter to X35CD
- Connect a DC voltmeter to P301
- Settings:
FREQUENCY 1000 MHz
FM1 DEVIATION 500 KHz
FM1 SOURCE LFGEN1
LFGEN1 FREQ 1 KHz
- Preset the control voltage at P301 to 7 V ± 1 V using C329.
- Preset frequency deviation to approx. 500 KHz using R490.
- The distortion factor is adjusted using R321. Due to the use of different deviation diodes, several distortion factor minima may arise on the characteristic, which is why the complete characteristic should be swept once and then set the point with minimum distortion factor, accordingly. The control voltage and the frequency deviation should be set to their rated values during distortion factor adjustment and afterwards.
- Subsequent to adjustment, the jumper X35 is fitted again.

7.4.3.3 Adjustment of the Control Voltage and the Frequency Deviation

The module must be covered by the screening cover for exact adjustment of the control voltage and the frequency deviation. Prior to adjustment, plug in all jumpers according to the circuit diagram.

It is assumed that the mixer module is working.

- Connect modulation analyzer to the RF output.
- Settings:
FREQUENCY 100 MHz
FM1 DEVIATION 62.5 KHz
FM1 SOURCE LFGEN1
LFGEN1 FREQ 1 KHz
- The control voltage can be read via the diagnosis 501. It is set to 7 V ± 0.25 V using C329.
- Set the frequency deviation to 62.5 KHz using R490.

7.4.3.4 Level Adjustment and Testing of the FM BUFFERS

- Settings:
FM1 DEVIATION 0 KHz
FM1 SOURCE EXT1
- The rated value at X35CD is 7 ± 1 dBm. It can be set using R345.
- Further rated levels and DC operating points in the RF path can be looked up according to 7.4.7.2.

7.4.4 Phase-locked Loop

(cf. circuit diagram, sheet 5)

The FM oscillator must have been adjusted prior to adjusting the PLL.

7.4.4.1 Adjustment of the PHIM Distortion Factor

- Settings:

FREQUENCY 100 MHz
PM1 DEVIATION 0.625 rad
PM1 SOURCE LFGEN1
LFGEN1 FREQ 1 KHz
- If the phase deviation is not set correctly, it is first preset to approx. 0.625 rad using R483.
- The distortion factor is adjusted to minimum using R444.

7.4.4.2 Adjustment of the Phase Deviation

- Connect a modulation analyzer to the RF output.

- Settings

FREQUENCY 100 MHz
PM1 DEVIATION 0.625 rad
PM1 SOURCE LFGEN1
LFGEN1 FREQ 1 KHz

- The phase deviation is set to 0.625 rad using R483.

7.4.4.3 Testing the PLL

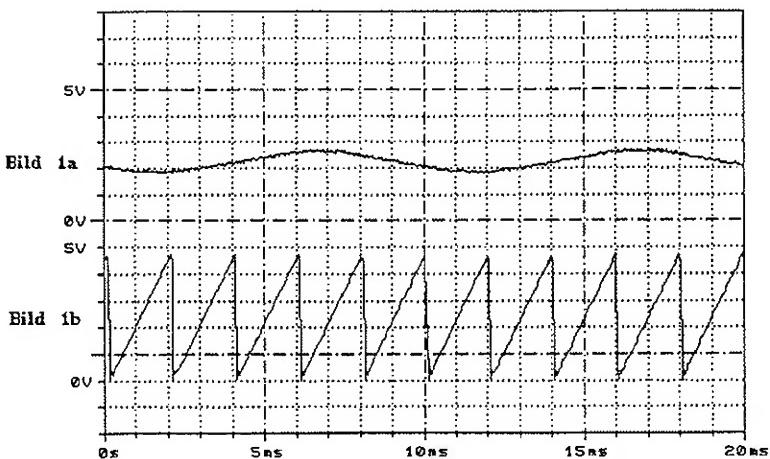

Check the subsequent voltages and signal characteristics at the test points listed below using a probe at the oscilloscope.

- Settings:
- | |
|-------------------------|
| FREQUENCY 100 MHz |
| PM1 DEVIATION 0.625 rad |
| PM1 SOURCE LFGEN1 |
| LFGEN1 FREQ 1 KHz |

Test point	Rated value	Remark
P400	5V	Supply voltage
P401	$2.25V + 0.75V_{ss}$	Pulses from phase difference + const. phase offset (subs. to lowpass) see fig. 1a
P403	ca. 5mV	Reset pulses subsequent to lowpass filtering
P301	approx. 7V	Control voltage
X37A X37B	$5V_{ss}$ $5V_{ss}$	TTL, 100 MHz modulated TTL, 100 MHz reference

When troubleshooting, we recommend that you open the PLL by removing jumper X49. To check the phase detector, apply a DC voltage to X49.3 and set it such that the RF output frequency is greater than 100 MHz. You should now see a sawtooth voltage at test point P403 as shown in figure 1b. If you change the applied DC voltage such that the output frequency drops below 100 MHz, you should see the sawtooth voltage at test point P401. The repetition frequency of the sawtooth voltage corresponds to the difference in frequency to the set 100 MHz.

Fig. 1a: Control loop locked in, AF = 1 KHz, deviation = 5 rad on board
Fig. 1b: Control loop not in order (P401 or P403)

7.4.5 Frequency Control Loop

(cf. circuit diagram, sheet 5)

Adjustment of the frequency control loop (7.4.5.1) requires prior adjustment of the FM OSCILLATOR. When checking the control loop it is assumed that the oscillator oscillates on 100 ± 0.5 MHz. If not, it must be set to this frequency using C329.

7.4.5.1 Adjustment of the FMAC Centre-Frequency Deviation

This adjustment can only be performed on modules having a revision index of AEI 04 or higher.

It is used to adjust VLF-dependent centre-frequency deviations which may occur due to asymmetries in the FM control loop.

First, with FM switched off, measure the output frequency. It is used as a reference value in the adjustment that follows.

- Connect spectrum analyzer to RF output
 - Connect LF output with EXT1 input
 - Settings
Reference meas.: FREQUENCY 1000 MHz
FM1 SOURCE OFF
FM2 SOURCE OFF
 - Settings
Adjustment: FM1 DEVIATION 500 KHz
FM1 SOURCE EXT1
EXT1 COUPLING AC
LF OUTPUT FREQ 1 KHz
VOLTAGE 1.000 V
- Using R437 and with modulation switched on, adjust the centre-frequency to the previously measured reference value.

7.4.5.2 Adjustment of the FM Correction

The module must be covered by the screening cover for adjustment of the FM correction. Prior to adjustment, all jumpers must be plugged in according to the circuit diagram. For modules having a revision index of AEI 04 or higher, the adjustment can only be carried out if the centre-frequency was previously adjusted according to 7.4.5.1.

- Connect DC voltage source 0 V, ± 1 V to EXT1
- Read in control voltage via diagnosis 501
- Settings:
 - FREQUENCY 1000 MHz
 - FM1 SOURCE EXT1
 - FM1 EXT COUPLING DC

The control voltage is measured with a DC voltage of 0 V. It is adjusted to minimum deviation with preset DC deviation. The deviation of the control voltage should be nearly identical with $+1$ V and -1 V set.

Frequency deviation FM1 DEVIATION	Adjustment element	Rel. variation of the tuning voltage
525 KHz	R429	$< \pm 15$ mV (up to AEI 03) $< \pm 5$ mV (AEI 04 or higher)
33 KHz	R427	$< \pm 2$ mV (up to AEI 03) $< \pm 1$ mV (AEI 04 or higher)

7.4.5.3 Testing the Control Loop

- Connect DC voltage source 0 V, ± 1 V to EXT1
- Settings:
 - FREQUENCY 1000 MHz
 - FM1 SOURCE EXT1
 - FM1 EXT COUPLING DC
 - FM1 DEVIATION 1000 KHz

Check the subsequent voltages and signal characteristics at the test points listed below using a probe on the oscilloscope.

Test point	Modulation voltage	Rated value	Remark
P301		7V	Control voltage *
P400		5V	Supply voltage for PHASE DETECTOR and FMDCSYNC
P401	$V_{mod}=1V$ $V_{mod}=-1V$	approx. 300mV _{ss} 5V _{ss}	Reset pulses subs. to lowpass filtering see fig. 2a Sawtooth voltage with difference frequency see fig. 3a
P402	$V_{mod}=1V$ $V_{mod}=-1V$	5V _{ss} 5V + about 300mV _{ss}	Sawtooth voltage with difference frequency see fig. 2b Reset pulses subs. to lowpass filtering see fig. 3b

Test point	Modulation voltage	Rated value	Remark
P404	$V_{mod}=1V$ $V_{mod}=-1V$	2.1V -2.1V	Modulation signal to loop integrator
P405	$V_{mod}=1V$ $V_{mod}=-1V$	TTL TTL	Pulses f. integrator see fig. 4a Pulse f. integrator see fig. 4b
P406 P407		5V -5V	Supply voltage for PULSE SWITCH Supply voltage for PULSE SWITCH
P408		7V	Tuning voltage for PHIM *
P409 P410		5V 5V	Output voltages window comparator with pulses with voltage difference *
X37A X37B		5V _{ss} 5V _{ss}	TTL, 100MHz modulated TTL, 100MHz reference

* The indicated voltages can only be verified if the control loop is locked.

When troubleshooting, we recommend that you open the control loop by removing jumper X36. To check the test points listed above, you should first make sure that the FM oscillator is oscillating at 100 ± 0.5 MHz. To do this, you can either retune the centre-frequency using C329 or apply an appropriate DC voltage to X36.2.

Fig. 2b: Test point P402, $V_{mod}=1V$

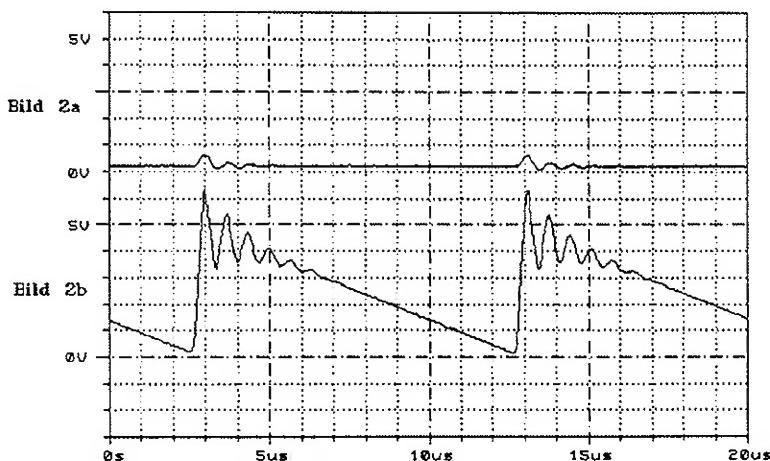

Fig. 3a: Test point P401, $V_{mod} = -1V$

Fig. 3b: Test point P402, $V_{mod} = -1V$

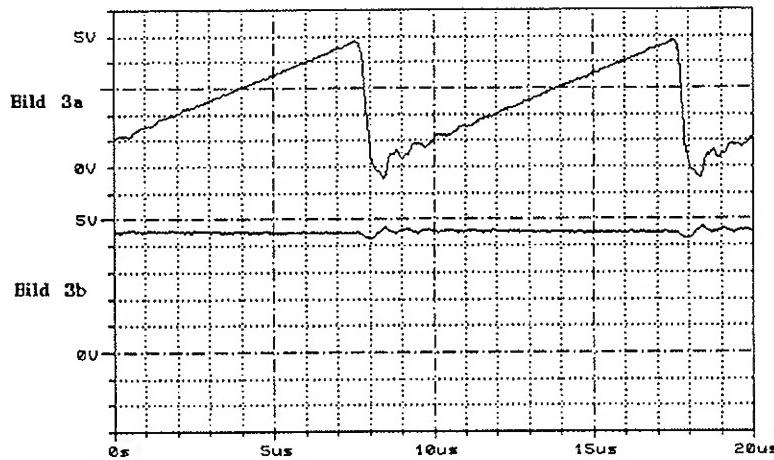

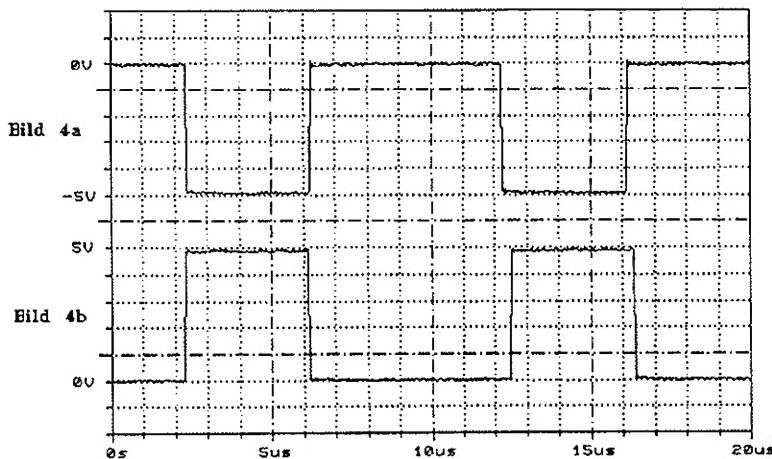

Fig. 4a: Test point P405, $V_{mod} = 1V$

Fig. 4b: Test point P405, $V_{mod} = -1V$

7.4.6 Mixer Stage

7.4.6.1 Testing the BANDPASS FILTER

- Remove jumper X35
- Carry out the check at X52AB or X57AB using a spectrum analyzer
- Settings:
 - FREQUENCY 1348.94 MHz
 - FM1 DEVIATION 0 KHz
 - FM1 SOURCE EXT1

Test point	RF level with 114.3606 MHz	RF level with 85.6394 MHz
X52AB	- 39 dBm	- 37 dBm
X57AB	- 29 dBm	≤ - 109 dBm

- Check of the DC operating points and the rated RF levels in the RF path can be carried out according to 7.4.7.3.

7.4.6.2 Testing BYPASS SWITCH and OUTPUT AMPLIFIER

The FM OSCILLATOR and the FM correction must be adjusted prior to testing the two modules.

- Connect DC voltage source + 1 V to EXT1.
- Connect spectrum analyzer to RF output
- Settings: **FREQUENCY 1348.94 MHz**
 LEVEL 0 dBm

Setting	RF level with 1348.94 MHz	RF level with 1349.94 MHz	DC voltage N595 Pin6
FM1 SOURCE EXT1 FM1 EXT COUPLING DC FM1 DEVIATION 1 MHz FM1/2 OFF	≤ - 80 dBm 0 dBm	0 dBm ≤ - 80 dBm	- 13 V 13 V

- Check of the DC operating points and the rated RF levels in the RF path can be carried out according to 7.4.7.3.

7.4.7 Tables and Interfaces

7.4.7.1 Digital Interface

Subaddress 0(Serout, CLK1, WR1):

Latch	Designation	Function			
D155	11	SWITCHMATRIX0		0=OFF	1=INT1-FM1
	12	SWITCHMATRIX1		0=OFF	1=EXT1-FM1
	13	SWITCHMATRIX2		0=OFF	1=EXT2-FM1
	14	SWITCHMATRIX3	Switch matrix for EXT1/2 and INT1/2 on FM1/2	0=OFF	1=EXT1-FM2
	7	SWITCHMATRIX4		0=OFF	1=EXT2-FM2
	6	SWITCHMATRIX5		0=OFF	1=INT2-FM2
	5	PREON	Preemphasis	0=OFF	1=ON
	4	PRE50/75		0=75μs	1=50μs

Latch		Designation	Function		
D150	11	FMDC	FM-DC/AC switch	0=FMAC	1=FMDC
	12	ACDC2	AC/DC switch	0=AC	1=DC
	13	ACDC1	for EXT1 and EXT2	0=AC	1=DC
	14	PHIMOD	FM/PHIM switch	0=FM	1=PHIM
	7	DIAG-ENA	Diagnosis on/off	0=OFF	1=ON
	6	DMUX2			MSB
	5	DMUX1	Diagnoses 0 to 7		LSB
	4	DMUX0			

Subaddress 1 (Serout, CLK2, WR2):

- Settings: FREQUENCY 1000 MHz
FM1 SOURCE EXT1
FM2 SOURCE EXT2

The individual bits are checked by setting the same frequency deviation for both channels. The deviation FM1 is set first.

Dev. setting in Hz	D165	D170	D175
	Pin 13 12 11	Pin 4 5 6 7 14 13 12 11	Pin 4 5 6 7 14 13 12 11

Diagnostic Points

Diagnostic pt.	Rated value	Specified range	Remark
500	0V	-10mV to 10mV	0V, 10 kOhm, reference
501	7V	2V to 13V	VCO tuning voltage with T = 25 °C
502	0.3V	0.1 to 0.5V	VCO output level, 100 MHz
503	0.25V	0.1 to 0.5V	LO level preceding 1st mixer, 100 MHz
504	0.25V	0.1 to 0.5V	Output level to sum. loop or Yig-P11 10.3 to 15.6 MHz
505	0V	-20 to 20mV	Modulation voltage (offset voltage)

7.5

Removal and Assembly

Subsequent to opening the instrument, unlocking the board and disconnecting the RF connections at X65, X67 and X69, the module can be taken out of its slot.

The screening covers of the board are conventionally screwed. With assembly, the screening cover on the component side should be screwed first. Otherwise, the threaded bolts which the threads are imbedded in, may shrink. If only the screening cover on the component side is removed, the screws of the screening cover on the solder side must at least be undone.

Pin	Name	Input/Output	Origin/Destin.	Specified range	Signal description

XY-Liste

XY List

Erklärung der Spaltenbezeichnungen:

el. Kennz.	Bauelement-Kennzeichen
Seite	Leiterplatten-Seite, auf der sich das Bauelement befindet
X/Y	Koordinaten (in Millimeter) des Bauelementes auf der Leiterplatte bezogen auf den Nullpunkt
Planq., Bl.	Planquadrat und Seite des Schaltbildes für das jeweilige Bauelement

Explanation of column designations:

Part	Identification of instrument part
Side	Side of the PC board on which instrument part is positioned
X/Y	Coordinates (in units of millimeters) of the component on the PC board in reference to zero point
Sqr, Pg	Square and page of the diagram for the respective instrument part
